

Chapter 10 – Sociotechnical Systems

Lecture 1

Topics covered

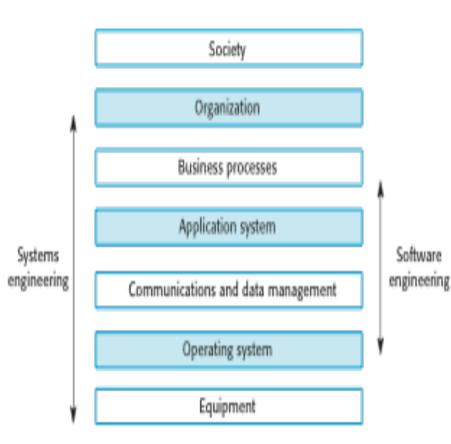

- ♦ Complex systems
- \diamond Systems engineering
- ♦ Systems procurement
- ♦ System development
- \diamond System operation

- Software engineering is not an isolated activity but is part of a broader systems engineering process.
- Software systems are essential components of broader systems that have <u>a human</u>, social or organizational <u>purpose</u>.
- ♦ Example
 - Wilderness weather system is part of broader weather recording and forecasting systems
 - These include hardware and software, forecasting processes, system users, the organizations that depend on weather forecasts, etc.

The sociotechnical systems stack

- Equipment: Hardware devices, embedded system
- ♦ Operating system
- ♦ Communications and data management
- ♦ Application systems: Specific functionality to meet some organization requirements.
- ♦ Business processes: A set of processes involving people and computer systems that support the activities of the business.
- ♦ Organizations: Higher level strategic business activities
- ♦ Society: Laws, regulation and culture

- There are interactions and dependencies between the layers in a system and changes at one level ripple through the other levels
 - Example: Change in regulations (society) leads to changes in business processes and application software.
- ♦ For dependability, a systems perspective is essential
 - Contain software failures within the enclosing layers of the sociotechnical system (STS) stack.
 - Understand how faults and failures in adjacent layers may affect the software in a system.

- A system is a purposeful collection of inter-related components working together to achieve some common objective.
- A system may include software, mechanical, electrical and electronic hardware and be operated by people.
- System components are <u>dependent on other</u> <u>system components</u>.
- The properties and behaviour of system components are inextricably inter-mingled. This leads to complexity.

♦ Technical computer-based systems

- Systems that include hardware and software but where the operators and operational processes are not normally considered to be part of the system. The system is not selfaware.
- Example: A word processor used to write a book.

♦ Socio-technical systems

- Systems that include technical systems but also <u>operational</u> <u>processes and people</u> who use and interact with the technical system. Socio-technical systems are governed by organisational policies and rules.
- Example: A publishing system to produce a book.

♦ Process changes

 Systems may require changes to business processes so <u>training</u> may be required. Significant changes may be resisted by users.

\diamond Job changes

 Systems may de-skill users or <u>cause changes to the way they</u> work. The status of individuals in an organization may be affected by the introduction of a new system.

♦ Organizational changes

 Systems may change the political power structure in an organization. If an organization depends on a system then those who control the system have more power.

♦ Emergent properties

- Properties of the system of a whole that depend on <u>the system</u> <u>components and their relationships</u>.
- ♦ Non-deterministic
 - They do not always produce the same output when presented with the same input because <u>the systems's behaviour is partially</u> <u>dependent on human operators</u>.

Complex relationships with organisational objectives

 The extent to which the system supports organisational objectives does not just depend on the system itself.

- Properties of the system as a whole, emergent properties are a consequence of the relationships between system components
- ♦ Functional properties
 - These appear when all the parts of a system work together to achieve some objective. For example, a bicycle has the functional property of being a transportation device once it has been assembled from its components.
- ♦ Non-functional emergent properties
 - Examples are reliability, performance, safety, and security. They are often critical for computer-based systems as failure to achieve some minimal defined level in these properties may make the system unusable

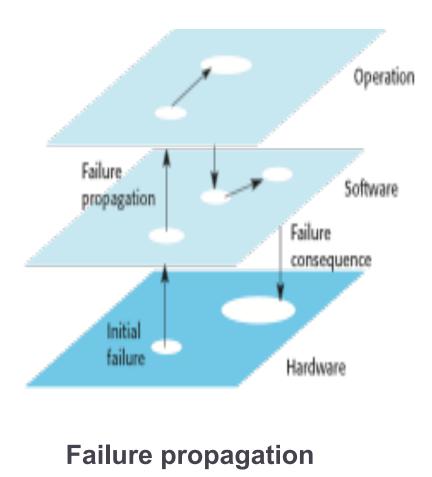

- Because of component inter-dependencies, faults can be propagated through the system.
- System failures often occur because of unforeseen interrelationships between components.
- It is practically impossible to anticipate all possible component relationships.
- Software reliability measures may give a false picture of the overall system reliability.

Influences on reliability

♦ Hardware reliability

- What is the probability of a hardware component failing and how long does it take to repair that component?
- ♦ Software reliability
 - How likely is it that a software component will produce an incorrect output.
- ♦ Operator reliability
 - How likely is it that the operator of a system will make an error?
- ♦ Failures are not independent and they propagate from one level to another.

- A deterministic system is one where <u>a given sequence of</u> <u>inputs will always produce the same sequence of</u> <u>outputs</u>.
- Software systems are deterministic; systems that include humans are non-deterministic
 - A socio-technical system will not always produce the same sequence of outputs from the same input sequence
 - Human elements
 - People do not always behave in the same way
 - System changes
 - System behaviour is unpredictable because of frequent changes to hardware, software and data.

- ♦ Complex systems are developed to address 'wicked problems' – problems where <u>there cannot be a complete</u> <u>specification</u>.
- Different stakeholders see the problem in different ways and each has a partial understanding of the issues affecting the system.
- Consequently, different stakeholders have their own views about whether or not a system is 'successful'
 - Success is a judgment and cannot be objectively measured.
 - Success is judged using the effectiveness of the system when deployed rather than judged against the original reasons for procurement.

MHC-PMS designed to support multiple, conflicting goals

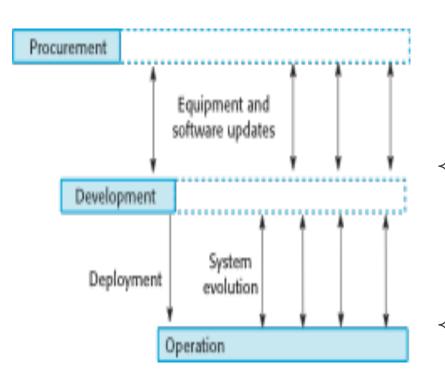

- Improve quality of care.
- Provide better information and care costs and so increase revenue.
- ♦ Fundamental conflict
 - To satisfy reporting goal, doctors and nurses had to provide additional information over and above that required for clinical purposes.
 - They had less time to interact with patients, so quality of care reduced. System was not a success.
- ♦ However, managers had better reports
 - System was a success from a managerial perspective.

- Procuring, specifying, designing, implementing, validating, deploying and maintaining socio-technical systems.
- Concerned with the services provided by the system, constraints on its construction and operation and the ways in which it is used to fulfill its purpose or purposes.

Stages of systems engineering

- ♦ Procurement (acquisition)
 - The purpose of the system is established, high-level system requirements are defined, decisions are made on how functionality is distributed and the system components are purchased.

♦ Development

 The system is developed – requirements are defined in detail, the system is implemented and tested and operational processes are defined.

♦ Operation

 The system is deployed and put into use. Changes are made as new requirements emerge. Eventually, the system is decommissioned.

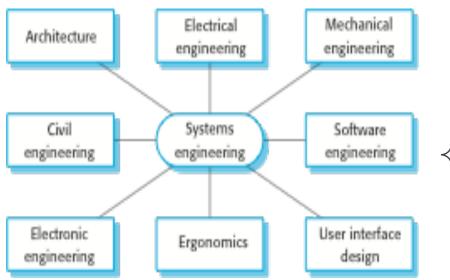

♦ Design options limited by procurement decisions

- Purchased components may make some safeguards impossible to implement.
- Inadequate testing may mean faults are not discovered before deployment.
- Assumptions made during procurement may be forgotten when system changes are made.

Professional disciplines involved in systems engineering

Inter-disciplinary working

♦ Communication difficulties

 Different disciplines use the same terminology to mean different things. This can lead to misunderstandings about what will be implemented.

♦ Differing assumptions

 Each discipline makes assumptions about what can and can't be done by other disciplines.

♦ Professional boundaries

 Each discipline tries to <u>protect</u> <u>their professional boundaries</u> and expertise and this affects their judgments on the system. meet some identified organizational need.

10.3 System procurement

- \diamond Before procurement, decisions are made on:
 - Scope of the system
 - System budgets and timescales
 - High-level system requirements
- \diamond Based on this information, decisions \diamond Available budget are made on whether to procure a system, the type of system and the potential system suppliers.

Decision drivers

- \diamond The state of other organizational systems
- \diamond The need to comply with external regulations
- ♦ External competition
- \diamond Business re-organization

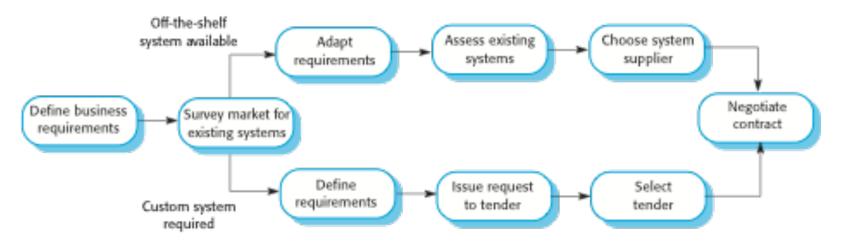

Some system specification and architectural design is usually necessary before procurement

- You need a specification to let a contract for system development
- The specification may allow you to buy a commercial off-theshelf (COTS) system. Almost always cheaper than developing a system from scratch

System procurement processes

- Requirements may have to be modified to match the capabilities of off-the-shelf components.
- ♦ The requirements specification may be part of the contract for the development of the system.
- There is usually a contract negotiation period to agree changes after the contractor to build a system has been selected.

- ♦ The procurement of large hardware/software systems is usually based around <u>some principal contractor</u>.
- Sub-contracts are issued to other suppliers to supply parts of the system.
- Customer relies on the principal contractor and does not deal directly with sub-contractors.

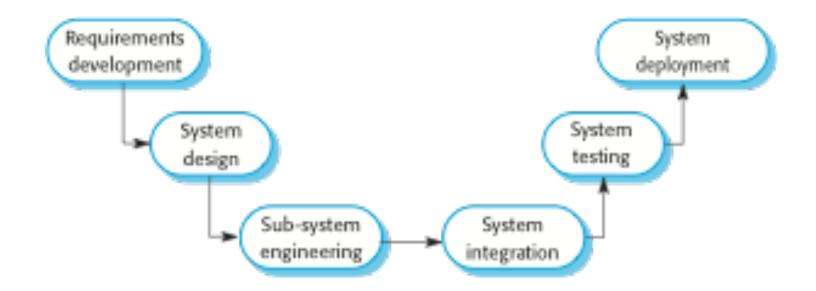

- Procurement decisions have profound effects on system dependability as these decisions limit the scope of dependability requirements.
- For an <u>off-the-shelf</u> system, the procurer has <u>very limited</u> <u>influence</u> on the security and dependability requirements of the system.
- ♦ For a <u>custom</u> system, <u>considerable effort has to be</u> <u>expended</u> in defining security and dependability requirements.

- Usually follows <u>a plan-driven approach</u> because of the need for parallel development of different parts of the system
 - Little scope for iteration between phases because hardware changes are very expensive. Software may have to compensate for hardware problems.
- Inevitably involves <u>engineers from different disciplines</u> who must work together
 - Much scope for <u>misunderstanding</u> here.
 - As explained, different disciplines use a <u>different vocabulary</u> and much <u>negotiation is required</u>. Engineers may have personal agendas to fulfil.

Systems development

Three types of requirement defined at this stage

- Abstract functional requirements. System functions are defined in an abstract way;
- System properties. Non-functional requirements for the system in general are defined;
- Undesirable characteristics. Unacceptable system behaviour is specified.

Should also define overall organisational objectives for the system.

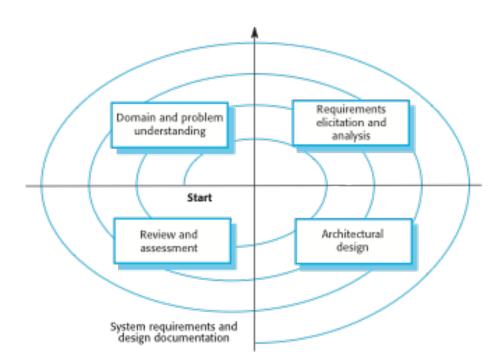

- ♦ Partition requirements
 - Organise requirements into related groups.
- \diamond Identify sub-systems
 - Identify a set of sub-systems which collectively can meet the system requirements.
- \diamond Assign requirements to sub-systems
 - Causes particular problems when COTS are integrated.
- ♦ Specify sub-system functionality.
- ♦ Define sub-system interfaces
 - Critical activity for parallel sub-system development.

Requirements and design

- Requirements engineering and system design are inextricably linked.
- Constraints posed by the system's environment and other systems limit design choices so the actual design to be used may be a requirement.
- Initial design may be necessary to structure the requirements.
- As you do design, you learn more about the requirements.

- Typically <u>parallel projects</u> developing the hardware, software and communications.
- Any involve some <u>COTS</u> (Commercial Off-the-Shelf) systems procurement.
- Lack of communication across implementation teams can cause problems.
- There may be <u>a bureaucratic and slow mechanism</u> for proposing system changes, which means that the development schedule may be extended because of the need for rework.

- The process of putting hardware, software and people together to make a system.
- Should ideally be tackled <u>incrementally</u> so that subsystems are integrated one at a time.
- \diamond The system <u>is tested</u> as it is integrated.
- ♦ Interface problems between sub-systems are usually found at this stage.
- Any be problems with uncoordinated deliveries of system components.

After completion, the system has to be installed in the customer's environment

- Environmental assumptions may be incorrect;
- May be <u>human resistance</u> to the introduction of a new system;
- System may have to <u>coexist with alternative systems</u> for some time;
- May be <u>physical installation problems</u> (e.g. cabling problems);
- <u>Data cleanup</u> may be required;
- <u>Operator training</u> has to be identified.

- ♦ Decisions are made on dependability and security requirements and trade-offs made between <u>costs</u>, <u>schedule</u>, <u>performance and dependability</u>.
- Human errors may lead to the introduction of faults into the system.
- Testing and validation processes may be limited because of limited budgets.
- Problems in deployment mean there may be a mismatch between the system and its operational environment.

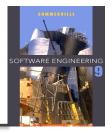

- Operational processes are the processes involved in <u>using the system</u> for its defined purpose.
- For new systems, these processes may have to be designed and tested and operators trained in the use of the system.
- Operational processes should be flexible to allow operators to cope with problems and periods of fluctuating workload.

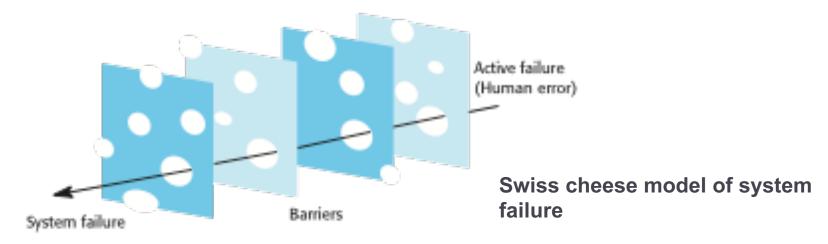

- ♦ Human errors occur in operational processes that influence the overall dependability of the system.
- \diamond Viewing human errors:
 - The person approach. Errors are considered to be the responsibility of the individual and "unsafe acts". Actions can reduce error include threats of punishment, better training, more stringent procedures, etc.
 - <u>The systems approach assumes that people are fallible and will</u> make mistakes. The system is designed to detect these mistakes before they lead to system failure. When a failure occurs, the aim is not to blame an individual but to understand why the system defenses did not trap the error. (RIGHT)

System defenses

- To improve security and dependability, designers should think about <u>the</u> <u>checks for human error</u> that should be included in a system.
- There should be multiple (redundant) barriers which should be different (diverse)
- \diamond No single barrier can be perfect.
 - There will be latent conditions in the system that may lead to failure.
- However, with multiple barriers, all have to fail for a system failure to occur.

- ♦ Conflict alert system
 - Raises an audible alarm when aircraft are on conflicting paths
- \diamond Recording of instructions
 - Allows instructions issues to be reviewed and checked.
- ♦ Sharing of information
 - The team of controllers cross-check each other's work.

- Large systems have a long lifetime. They <u>must evolve</u> to meet changing requirements.
- ♦ Evolution is inherently costly
 - Changes must be analysed from <u>a technical and business</u> perspective;
 - Sub-systems interact so <u>unanticipated problems</u> can arise;
 - There is rarely a rationale for original design decisions;
 - System structure is corrupted as changes are made to it.
- Existing systems which must be maintained are sometimes called <u>legacy systems</u>.

- ♦ <u>Changes</u> to a system <u>are often a source of problems</u> and vulnerabilities.
- Changes may be made without knowledge of previous design decisions made for security and dependability reasons.
 - Built-in safeguards may stop working.
- ♦ <u>New faults may be introduced</u> or latent faults exposed by changes.
 - These may not be discovered because complete system retesting is too expensive.

- Socio-technical systems include computer hardware, software and people and are designed to meet some business goal.
- Human and organizational factors, such as the organizational structure, have a significant effect on the operation of socio-technical systems.
- Emergent properties are properties that are characteristic of the system as a whole and not its component parts.
- The fundamental stages of systems engineering are procurement, development and operation.

- System procurement covers all of the activities involved in deciding what system to buy and who should supply that system.
- System development includes requirements specification, design, construction, integration and testing.
- When a system is put into use, the operational processes and the system itself have to change to reflect changing business requirements.
- Human errors are inevitable and systems should include barriers to detect these errors before they lead to system failure.
