# Chapter 5 Link Layer

KUROSE ROSS

#### A note on the use of these ppt slides:

We're making these slides freely available to all (faculty, students, readers). They're in PowerPoint form so you see the animations; and can add, modify, and delete slides (including this one) and slide content to suit your needs. They obviously represent a lot of work on our part. In return for use, we only ask the following:

- If you use these slides (e.g., in a class) that you mention their source (after all, we'd like people to use our book!)
- If you post any slides on a www site, that you note that they are adapted from (or perhaps identical to) our slides, and note our copyright of this material.

Thanks and enjoy! JFK/KWR

## Chapter 5: Link layer

#### our goals:

- understand principles behind link layer services:
  - error detection, correction
  - sharing a broadcast channel: multiple access
  - link layer addressing
  - local area networks: Ethernet, VLANs
- instantiation, implementation of various link layer technologies

## Link layer, LANs: outline

- 5.1 introduction, services
- 5.2 error detection, correction
- 5.3 multiple access protocols
- **5.4** LANs
  - addressing, ARP
  - Ethernet
  - switches
  - VLANS

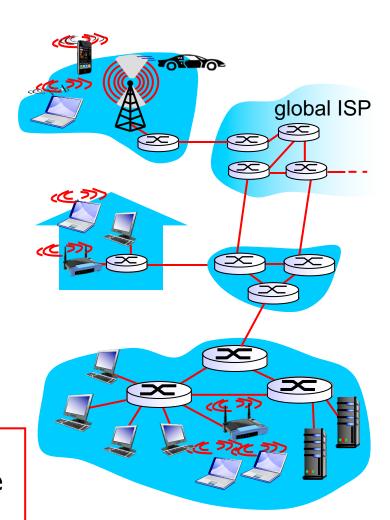

- 5.5 link virtualization: MPLS
- 5.6 data center networking
- 5.7 a day in the life of a web request

## Link layer: introduction

#### terminology:

- hosts and routers: nodes
- communication channels that connect adjacent nodes along communication path: links
  - wired links
  - wireless links
  - LANs
- layer-2 packet: frame, encapsulates datagram

data-link layer has responsibility of transferring datagram from one node to physically adjacent node over a link

## Link layer: context

- datagram transferred by different link protocols over different links:
  - e.g., Ethernet on first link, frame relay on intermediate links, 802.11 on last link
- each link protocol provides different services
  - e.g., may or may not provide rdt over link

#### transportation analogy:

- trip from Princeton to Lausanne
  - limo: Princeton to JFK
  - plane: JFK to Geneva
  - train: Geneva to Lausanne
- tourist = datagram
- transport segment = communication link
- transportation mode = link layer protocol
- travel agent = routing algorithm

## Link layer services

- framing, link access:
  - encapsulate datagram into frame, adding header, trailer
  - channel access if shared medium
  - "MAC" addresses used in frame headers to identify source, dest
    - different from IP address!
- reliable delivery between adjacent nodes
  - we learned how to do this already (chapter 3)!
  - seldom used on low bit-error link (fiber, some twisted pair)
  - wireless links: high error rates
    - Q: why both link-level and end-end reliability?

# Link layer services (more)

#### flow control:

pacing between adjacent sending and receiving nodes

#### error detection:

- errors caused by signal attenuation, noise.
- receiver detects presence of errors:
  - signals sender for retransmission or drops frame

#### error correction:

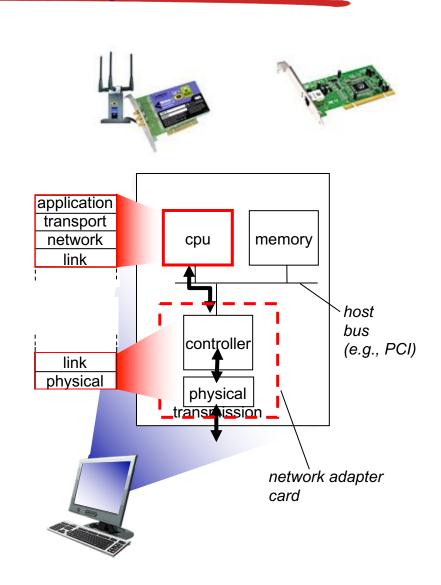

receiver identifies and corrects bit error(s) without resorting to retransmission

#### half-duplex and full-duplex

 with half duplex, nodes at both ends of link can transmit, but not at same time

### Where is the link layer implemented?

- in each and every host
- link layer implemented in "adaptor" (aka network interface card NIC) or on a chip
  - Ethernet card, 802.11 card; Ethernet chipset
  - implements link, physical layer
- attaches into host's system buses
- combination of hardware, software, firmware

# Adaptors communicating

- sending side:
  - encapsulates datagram in frame
  - adds error checking bits, rdt, flow control, etc.

- receiving side
  - looks for errors, rdt, flow control, etc
  - extracts datagram, passes to upper layer at receiving side

### Link layer, LANs: outline

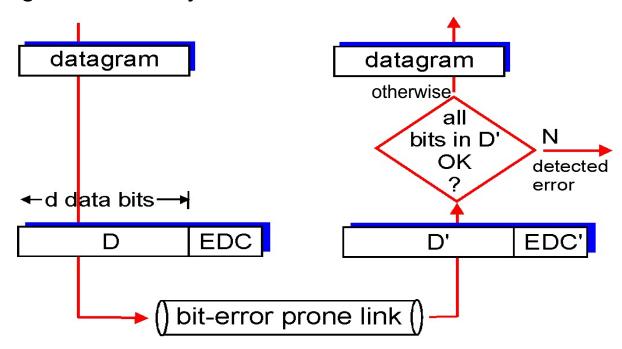

- 5.1 introduction, services
- 5.2 error detection, correction
- 5.3 multiple access protocols
- **5.4** LANs
  - addressing, ARP
  - Ethernet
  - switches
  - VLANS

- 5.5 link virtualization: MPLS
- 5.6 data center networking
- 5.7 a day in the life of a web request

#### **Error detection**

EDC= Error Detection and Correction bits (redundancy)

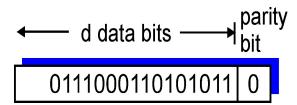

- D = Data protected by error checking, may include header fields
- Error detection not 100% reliable!
  - protocol may miss some errors, but rarely
  - larger EDC field yields better detection and correction

# Parity checking

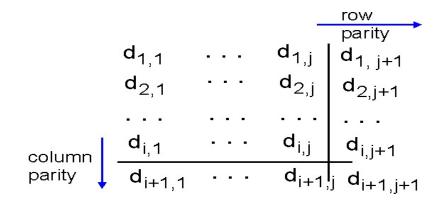

#### single bit parity:

\* detect single bit errors

#### two-dimensional bit parity:

detect and correct single bit errors

single bit error

# Internet checksum (review)

goal: detect "errors" (e.g., flipped bits) in transmitted packet (note: used at transport layer only)

#### sender:

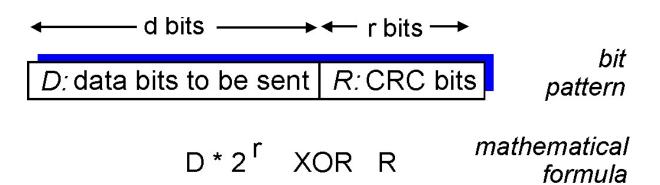

- treat segment contents as sequence of 16-bit integers
- checksum: addition (l's complement sum) of segment contents
- sender puts checksum value into UDP checksum field

#### receiver:

- compute checksum of received segment
- check if computed checksum equals checksum field value:
  - NO error detected
  - YES no error detected. But maybe errors nonetheless?

### Cyclic redundancy check

- more powerful error-detection coding
- view data bits, D, as a binary number
- choose r+1 bit pattern (generator), G
- goal: choose r CRC bits, R, such that
  - <D,R> exactly divisible by G (modulo 2)
  - receiver knows G, divides <D,R> by G. If non-zero remainder: error detected!
  - can detect all burst errors less than r+1 bits
- widely used in practice (Ethernet, 802.11 WiFi, ATM)

### CRC example

#### want:

 $D \cdot 2^r XOR R = nG$ 

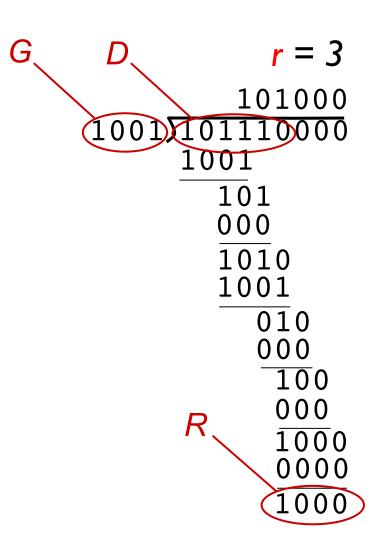

equivalently:

 $D \cdot 2^r = nG XOR R$ 

#### equivalently:

if we divide D.2<sup>r</sup> by G, want remainder R to satisfy:

$$R = remainder[\frac{D \cdot 2^r}{G}]$$

## Link layer, LANs: outline

- 5.1 introduction, services
- 5.2 error detection, correction
- 5.3 multiple access protocols
- **5.4** LANs
  - addressing, ARP
  - Ethernet
  - switches
  - VLANS

- 5.5 link virtualization: MPLS
- 5.6 data center networking
- 5.7 a day in the life of a web request

### Multiple access links, protocols

#### two types of "links":

- point-to-point
  - PPP for dial-up access
  - point-to-point link between Ethernet switch, host
- broadcast (shared wire or medium)
  - old-fashioned Ethernet
  - upstream HFC
  - 802.11 wireless LAN

shared wire (e.g., cabled Ethernet)

shared RF (e.g., 802.11 WiFi)

shared RF (satellite)

humans at a cocktail party (shared air, acoustical)

## Multiple access protocols

- single shared broadcast channel
- two or more simultaneous transmissions by nodes: interference
  - collision if node receives two or more signals at the same time

#### multiple access protocol

- distributed algorithm that determines how nodes share channel, i.e., determine when node can transmit
- communication about channel sharing must use channel itself!
  - no out-of-band channel for coordination

### An ideal multiple access protocol

given: broadcast channel of rate R bps desiderata:

- I. when one node wants to transmit, it can send at rate R.
- 2. when M nodes want to transmit, each can send at average rate R/M
- 3. fully decentralized:
  - no special node to coordinate transmissions
  - no synchronization of clocks, slots
- 4. simple

### MAC protocols: taxonomy

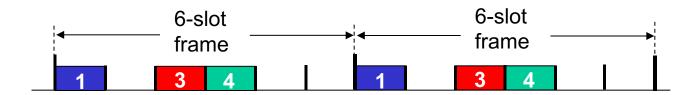

#### three broad classes:

- channel partitioning
  - divide channel into smaller "pieces" (time slots, frequency, code)
  - allocate piece to node for exclusive use
- random access
  - channel not divided, allow collisions
  - "recover" from collisions
- "taking turns"
  - nodes take turns, but nodes with more to send can take longer turns

### Channel partitioning MAC protocols: TDMA

#### TDMA: time division multiple access

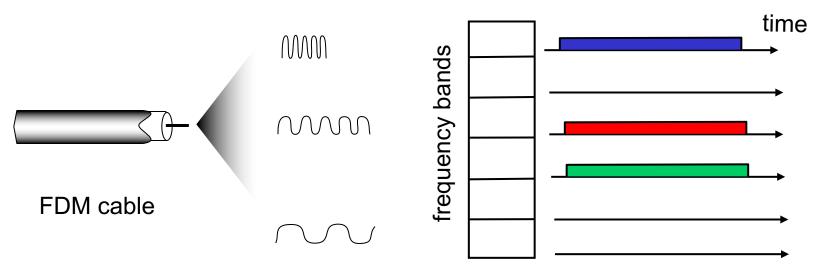

- access to channel in "rounds"
- each station gets fixed length slot (length = pkt trans time) in each round
- unused slots go idle
- example: 6-station LAN, 1,3,4 have pkt, slots 2,5,6 idle

### Channel partitioning MAC protocols: FDMA

#### FDMA: frequency division multiple access

- channel spectrum divided into frequency bands
- each station assigned fixed frequency band
- unused transmission time in frequency bands go idle
- example: 6-station LAN, 1,3,4 have pkt, frequency bands 2,5,6 idle

### Random access protocols

- when node has packet to send
  - transmit at full channel data rate R.
  - no a priori coordination among nodes
- ❖ two or more transmitting nodes → "collision",
- random access MAC protocol specifies:
  - how to detect collisions
  - how to recover from collisions (e.g., via delayed retransmissions)
- examples of random access MAC protocols:
  - slotted ALOHA
  - ALOHA
  - CSMA, CSMA/CD, CSMA/CA

### Slotted ALOHA

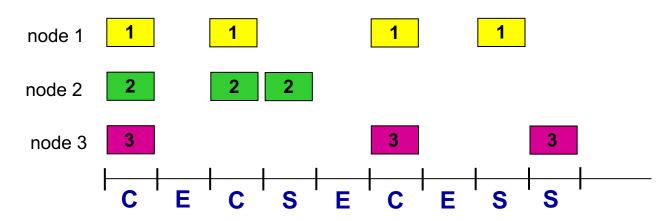

#### assumptions:

- all frames same size
- time divided into equal size slots (time to transmit I frame)
- nodes start to transmit only slot beginning
- nodes are synchronized
- if 2 or more nodes transmit in slot, all nodes detect collision

#### operation:

- when node obtains fresh frame, transmits in next slot
  - if no collision: node can send new frame in next slot
  - if collision: node retransmits frame in each subsequent slot with prob. p until success

### Slotted ALOHA

#### **Pros:**

- single active node can continuously transmit at full rate of channel
- highly decentralized: only slots in nodes need to be in sync
- simple

#### Cons:

- collisions, wasting slots
- idle slots
- nodes may be able to detect collision in less than time to transmit packet
- clock synchronization

## Slotted ALOHA: efficiency

efficiency: long-run fraction of successful slots (many nodes, all with many frames to send)

- suppose: N nodes with many frames to send, each transmits in slot with probability p
- \* prob that given node has success in a slot =  $p(1-p)^{N-1}$
- \* prob that any node has a success =  $Np(1-p)^{N-1}$

- max efficiency: find p\* that maximizes Np(I-p)<sup>N-I</sup>
- for many nodes, take limit of Np\*(I-p\*)<sup>N-I</sup> as N goes to infinity, gives:

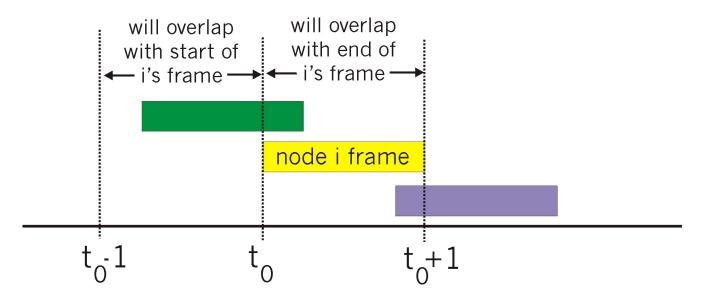

max efficiency = 1/e = .37

at best: channel used for useful transmissions 37% of time!

## Pure (unslotted) ALOHA

- unslotted Aloha: simpler, no synchronization
- when frame first arrives
  - transmit immediately
- collision probability increases:
  - frame sent at  $t_0$  collides with other frames sent in  $[t_0-1,t_0+1]$

## Pure ALOHA efficiency

P(success by given node) = P(node transmits)

P(no other node transmits in  $[t_0-1,t_0]$  · P(no other node transmits in  $[t_0-1,t_0]$ 

= 
$$p \cdot (I-p)^{N-1} \cdot (I-p)^{N-1}$$
  
=  $p \cdot (I-p)^{2(N-1)}$ 

... choosing optimum p and then letting n  $\rightarrow \infty$ = 1/(2e) = .18

even worse than slotted Aloha!

### CSMA (carrier sense multiple access)

**CSMA**: listen before transmit:

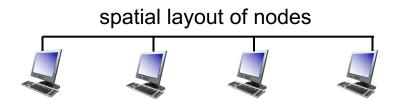

if channel sensed idle: transmit entire frame

if channel sensed busy, defer transmission

human analogy: don't interrupt others!

### **CSMA** collisions

- collisions can still occur: propagation delay means two nodes may not hear each other's transmission
- collision: entire packet transmission time wasted
  - distance & propagation delay play role in in determining collision probability

 $\mathsf{t}_{_{1}}$ 

# CSMA/CD (collision detection)

#### CSMA/CD: carrier sensing, deferral as in CSMA

- collisions detected within short time
- colliding transmissions aborted, reducing channel wastage
- collision detection:
  - easy in wired LANs: measure signal strengths, compare transmitted, received signals
  - difficult in wireless LANs: received signal strength overwhelmed by local transmission strength
- human analogy: the polite conversationalist

# CSMA/CD (collision detection)

### Ethernet CSMA/CD algorithm

- I. NIC receives datagram from network layer, creates frame
- 2. If NIC senses channel idle, starts frame transmission. If NIC senses channel busy, waits until channel idle, then transmits.
- 3. If NIC transmits entire frame without detecting another transmission, NIC is done with frame!

- 4. If NIC detects another transmission while transmitting, aborts and sends jam signal
- 5. After aborting, NIC enters binary (exponential) backoff:
  - after mth collision, NIC chooses K at random from {0,1,2, ..., 2<sup>m</sup>-1}. NIC waits K·512 bit times, returns to Step 2
  - longer backoff interval with more collisions

# CSMA/CD efficiency

- $\star$  T<sub>prop</sub> = max prop delay between 2 nodes in LAN
- $\star$   $t_{trans}$  = time to transmit max-size frame

$$efficiency = \frac{1}{1 + 5t_{prop}/t_{trans}}$$

- efficiency goes to I
  - as t<sub>prop</sub> goes to 0
  - as t<sub>trans</sub> goes to infinity
- better performance than ALOHA: and simple, cheap, decentralized!

# "Taking turns" MAC protocols

#### channel partitioning MAC protocols:

- share channel efficiently and fairly at high load
- inefficient at low load: delay in channel access, I/N bandwidth allocated even if only I active node!

#### random access MAC protocols

- efficient at low load: single node can fully utilize channel
- high load: collision overhead

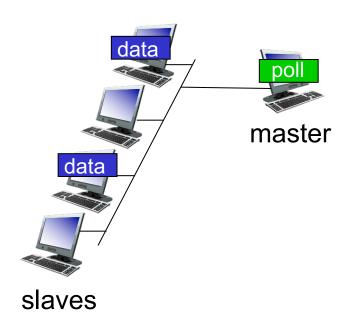

#### "taking turns" protocols

look for best of both worlds!

# "Taking turns" MAC protocols

#### polling:

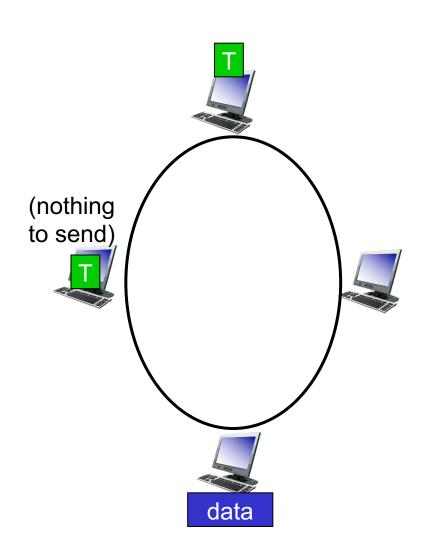

- master node "invites" slave nodes to transmit in turn
- typically used with "dumb" slave devices
- concerns:
  - polling overhead
  - latency
  - single point of failure (master)

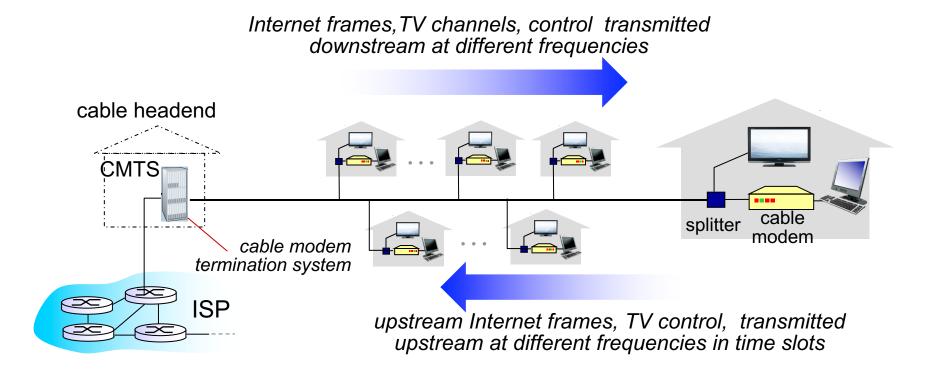

# "Taking turns" MAC protocols

#### token passing:

- control token passed from one node to next sequentially.
- token message
- concerns:
  - token overhead
  - latency
  - single point of failure (token)

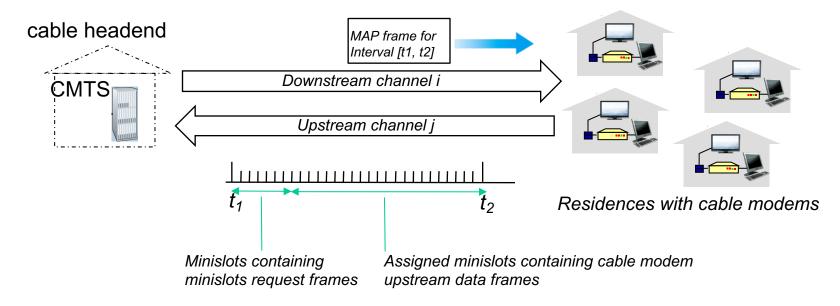

#### Cable access network

- multiple 40Mbps downstream (broadcast) channels
  - single CMTS transmits into channels
- multiple 30 Mbps upstream channels
  - multiple access: all users contend for certain upstream channel time slots (others assigned)

#### Cable access network

#### DOCSIS: data over cable service interface spec

- FDM over upstream, downstream frequency channels
- TDM upstream: some slots assigned, some have contention
  - downstream MAP frame: assigns upstream slots
  - request for upstream slots (and data) transmitted random access (binary backoff) in selected slots

# Summary of MAC protocols

- channel partitioning, by time, frequency or code
  - Time Division, Frequency Division
- random access (dynamic),
  - ALOHA, S-ALOHA, CSMA, CSMA/CD
  - carrier sensing: easy in some technologies (wire), hard in others (wireless)
  - CSMA/CD used in Ethernet
  - CSMA/CA used in 802.11
- taking turns
  - polling from central site, token passing
  - bluetooth, FDDI, token ring

# Link layer, LANs: outline

- 5.1 introduction, services
- 5.2 error detection, correction
- 5.3 multiple access protocols
- 5.4 LANs
  - addressing, ARP
  - Ethernet
  - switches
  - VLANS

- 5.5 link virtualization: MPLS
- 5.6 data center networking
- 5.7 a day in the life of a web request

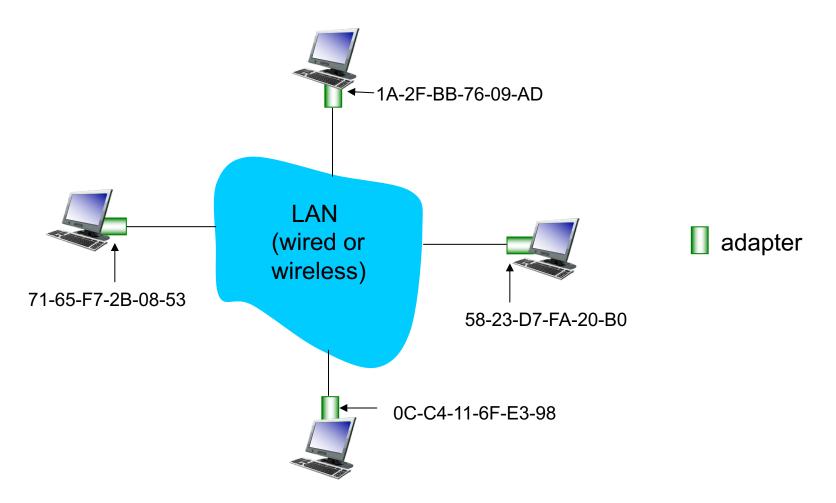

### MAC addresses and ARP

- 32-bit IP address:
  - network-layer address for interface
  - used for layer 3 (network layer) forwarding
- MAC (or LAN or physical or Ethernet) address:
  - function: used 'locally" to get frame from one interface to another physically-connected interface (same network, in IPaddressing sense)
  - 48 bit MAC address (for most LANs) burned in NIC ROM, also sometimes software settable
  - e.g.: IA-2F-BB-76-09-AD

hexadecimal (base 16) notation (each "number" represents 4 bits)

### LAN addresses and ARP

#### each adapter on LAN has unique LAN address

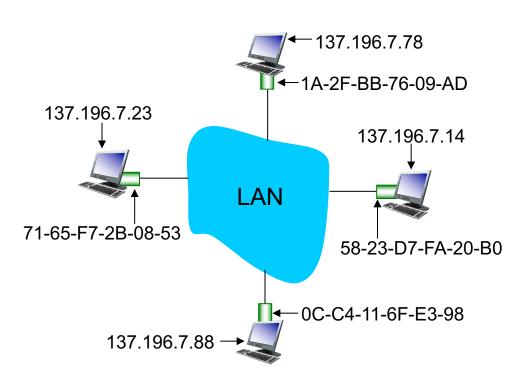

# LAN addresses (more)

- MAC address allocation administered by IEEE
- manufacturer buys portion of MAC address space (to assure uniqueness)
- analogy:
  - MAC address: like Social Security Number
  - IP address: like postal address
- ♦ MAC flat address → portability
  - can move LAN card from one LAN to another
- IP hierarchical address not portable
  - address depends on IP subnet to which node is attached

## ARP: address resolution protocol

Question: how to determine interface's MAC address, knowing its IP address?

ARP table: each IP node (host, router) on LAN has table

- IP/MAC address mappings for some LAN nodes:
  - < IP address; MAC address; TTL>
- TTL (Time To Live): time after which address mapping will be forgotten (typically 20 min)

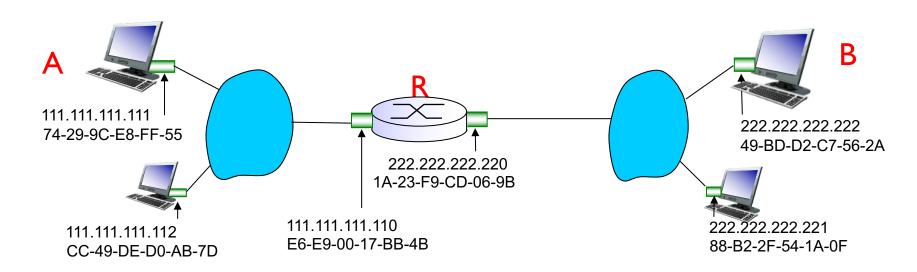

# ARP protocol: same LAN

- A wants to send datagram to B
  - B's MAC address not in A's ARP table.
- A broadcasts ARP query packet, containing B's IP address
  - dest MAC address = FF-FF-FF-FF-FF
  - all nodes on LAN receive ARP query
- B receives ARP packet, replies to A with its (B's) MAC address
  - frame sent to A's MAC address (unicast)

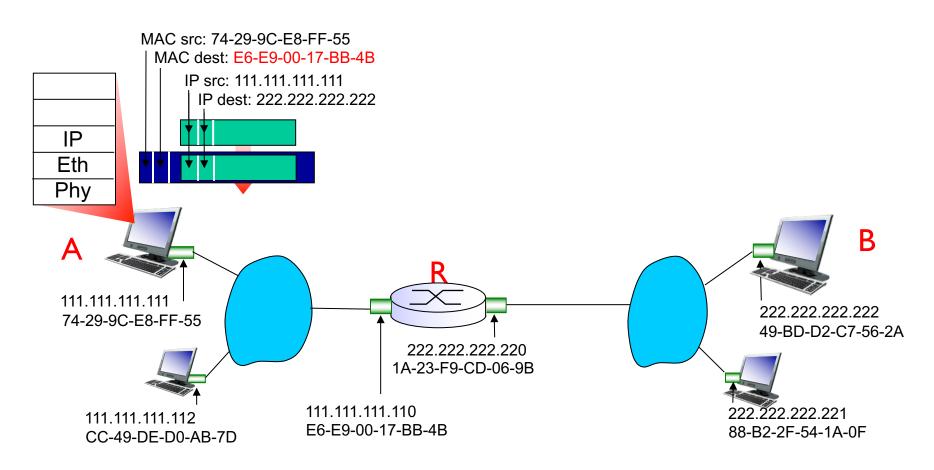

- A caches (saves) IP-to-MAC address pair in its ARP table until information becomes old (times out)
  - soft state: information that times out (goes away) unless refreshed
- ARP is "plug-and-play":
  - nodes create their ARP tables without intervention from net administrator

#### walkthrough: send datagram from A to B via R

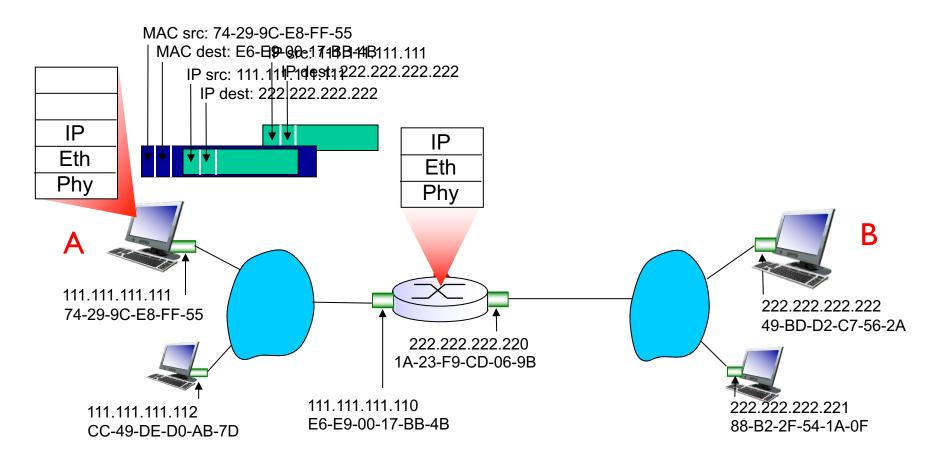

- focus on addressing at IP (datagram) and MAC layer (frame)
- assume A knows B's IP address
- assume A knows IP address of first hop router, R (how?)
- assume A knows R's MAC address (how?)

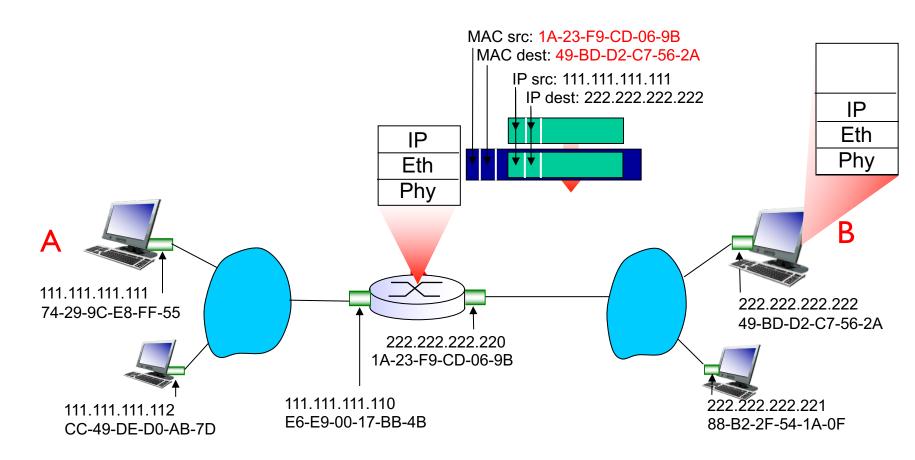

- A creates IP datagram with IP source A, destination B
- A creates link-layer frame with R's MAC address as dest, frame contains A-to-B IP datagram

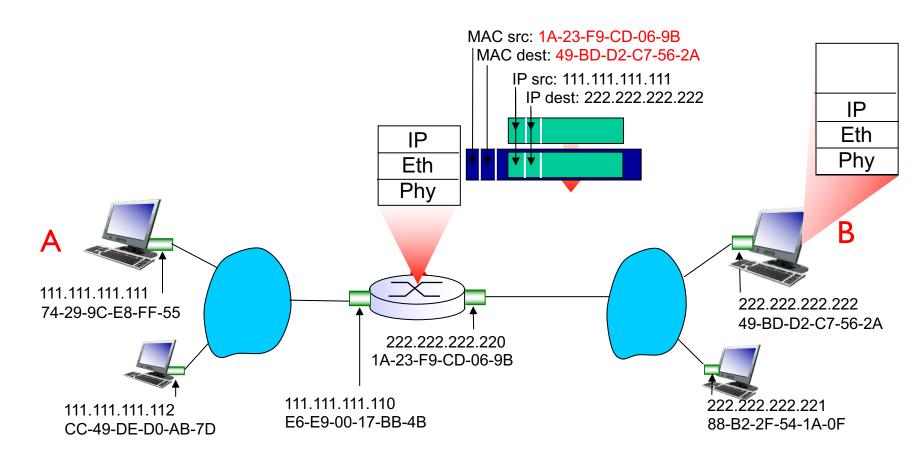

- frame sent from A to R
- frame received at R, datagram removed, passed up to IP

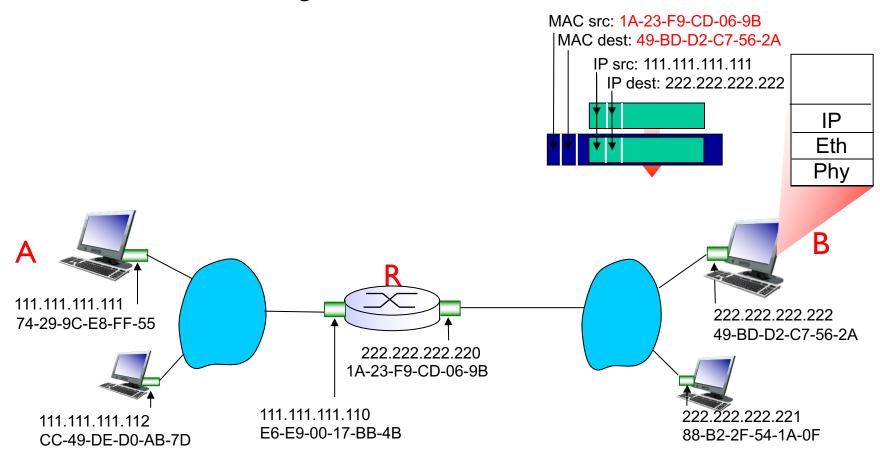

- R forwards datagram with IP source A, destination B
- R creates link-layer frame with B's MAC address as dest, frame contains A-to-B IP datagram

- R forwards datagram with IP source A, destination B
- R creates link-layer frame with B's MAC address as dest, frame contains A-to-B IP datagram

- R forwards datagram with IP source A, destination B
- R creates link-layer frame with B's MAC address as dest, frame contains A-to-B IP datagram

# Link layer, LANs: outline

- 5.1 introduction, services
- 5.2 error detection, correction
- 5.3 multiple access protocols

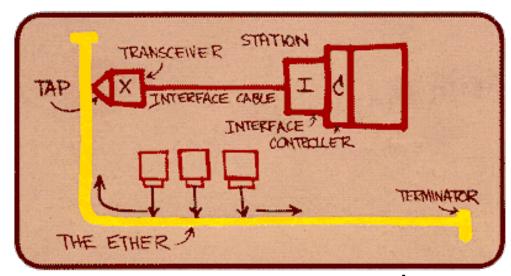

#### 5.4 LANs

- addressing, ARP
- Ethernet
- switches
- VLANS

- 5.5 link virtualization: MPLS
- 5.6 data center networking
- 5.7 a day in the life of a web request

# Ethernet

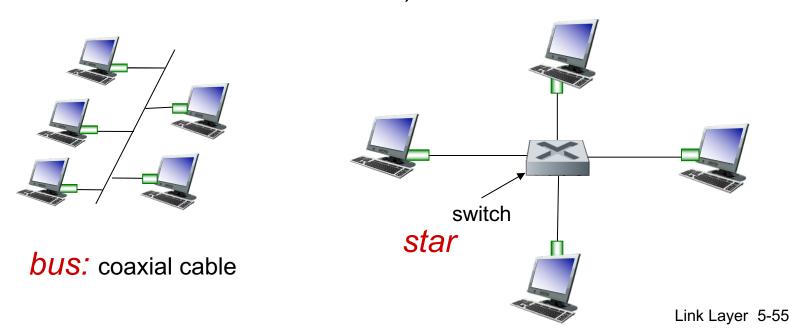

- "dominant" wired LAN technology:
- cheap \$20 for NIC
- first widely used LAN technology
- simpler, cheaper than token LANs and ATM
- kept up with speed race: 10 Mbps 10 Gbps

Metcalfe's Ethernet sketch

## Ethernet: physical topology

- bus: popular through mid 90s
  - all nodes in same collision domain (can collide with each other)
- star: prevails today
  - active switch in center
  - each "spoke" runs a (separate) Ethernet protocol (nodes do not collide with each other)

#### Ethernet frame structure

sending adapter encapsulates IP datagram (or other network layer protocol packet) in Ethernet frame

type

			<u> </u>		
preamble	dest. address	source address		data (payload)	CRC

#### preamble:

- 7 bytes with pattern 10101010 followed by one byte with pattern 10101011
- used to synchronize receiver, sender clock rates

### Ethernet frame structure (more)

- addresses: 6 byte source, destination MAC addresses
  - if adapter receives frame with matching destination address, or with broadcast address (e.g. ARP packet), it passes data in frame to network layer protocol
  - otherwise, adapter discards frame
- \* type: indicates higher layer protocol (mostly IP but others possible, e.g., Novell IPX, AppleTalk)
- \* CRC: cyclic redundancy check at receiver
  - error detected: frame is dropped

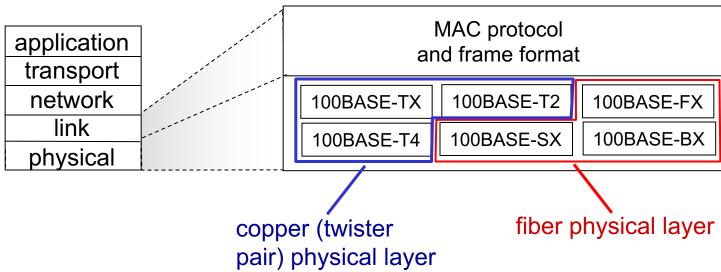

#### Ethernet: unreliable, connectionless

- connectionless: no handshaking between sending and receiving NICs
- unreliable: receiving NIC doesnt send acks or nacks to sending NIC
  - data in dropped frames recovered only if initial sender uses higher layer rdt (e.g., TCP), otherwise dropped data lost
- Ethernet's MAC protocol: unslotted CSMA/CD wth binary backoff

#### 802.3 Ethernet standards: link & physical layers

- many different Ethernet standards
  - common MAC protocol and frame format
  - different speeds: 2 Mbps, 10 Mbps, 100 Mbps, 1Gbps, 10G bps
  - different physical layer media: fiber, cable

# Link layer, LANs: outline

- 5.1 introduction, services
- 5.2 error detection, correction
- 5.3 multiple access protocols

#### **5.4 LANs**

- addressing, ARP
- Ethernet
- switches
- VLANS

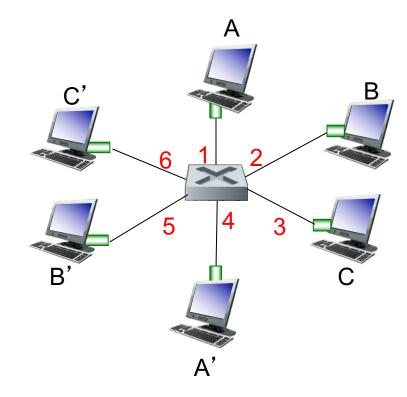

- 5.5 link virtualization: MPLS
- 5.6 data center networking
- 5.7 a day in the life of a web request

## Ethernet switch

- link-layer device: takes an active role
  - store, forward Ethernet frames
  - examine incoming frame's MAC address, selectively forward frame to one-or-more outgoing links when frame is to be forwarded on segment, uses CSMA/CD to access segment
- transparent
  - hosts are unaware of presence of switches
- plug-and-play, self-learning
  - switches do not need to be configured

#### Switch: multiple simultaneous transmissions

- hosts have dedicated, direct connection to switch
- switches buffer packets
- Ethernet protocol used on each incoming link, but no collisions; full duplex
  - each link is its own collision domain
- switching: A-to-A' and B-to-B' can transmit simultaneously, without collisions

switch with six interfaces (1,2,3,4,5,6)

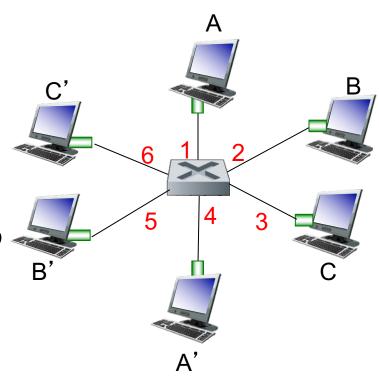

#### Switch forwarding table

Q: how does switch know A' reachable via interface 4, B' reachable via interface 5?

- \* A: each switch has a switch table, each entry:
  - (MAC address of host, interface to reach host, time stamp)
  - looks like a routing table!

**Q**: how are entries created, maintained in switch table?

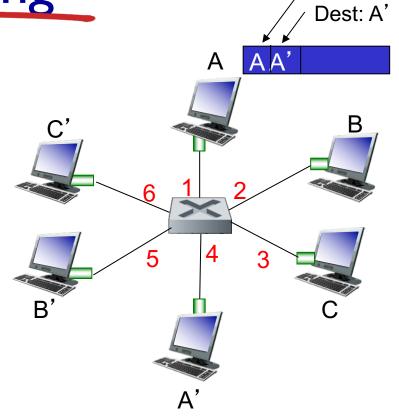

something like a routing protocol?

switch with six interfaces (1,2,3,4,5,6)

# Switch: self-learning

- switch learns which hosts can be reached through which interfaces
  - when frame received, switch "learns" location of sender: incoming LAN segment
  - records sender/location pair in switch table

MAC addr	interface	TTL	
Α	1	60	

Switch table (initially empty)

Source: A

# Switch: frame filtering/forwarding

#### when frame received at switch:

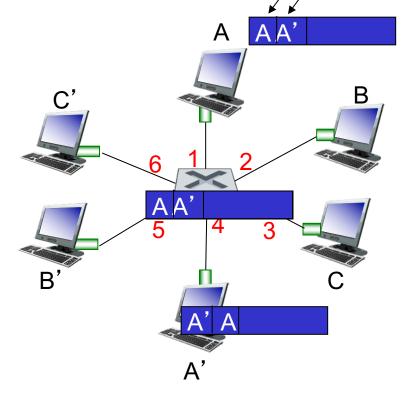

- I. record incoming link, MAC address of sending host
- 2. index switch table using MAC destination address

```
3. if entry found for destination then {
if destination on segment from which frame arrived then drop frame
else forward frame on interface indicated by entry
}
else flood /* forward on all interfaces except arriving interface */
```

### Self-learning, forwarding: example

Source: A Dest: A'

- frame destination, A', locaton unknown: flood
- destination A location known: selectively send on just one link

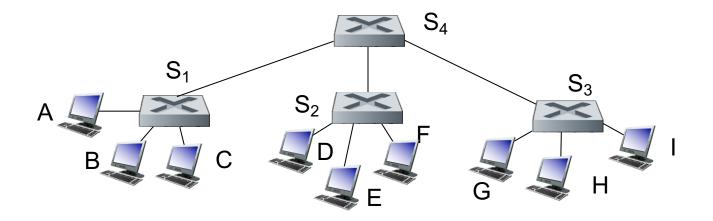

MAC addr	interface	TTL
Α	1	60
Α'	4	60

switch table (initially empty)

## Interconnecting switches

switches can be connected together

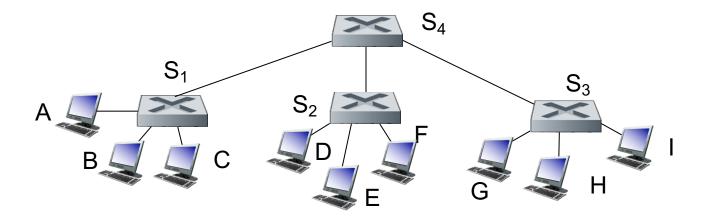

Q: sending from A to G - how does  $S_1$  know to forward frame destined to F via  $S_4$  and  $S_3$ ?

A: self learning! (works exactly the same as in single-switch case!)

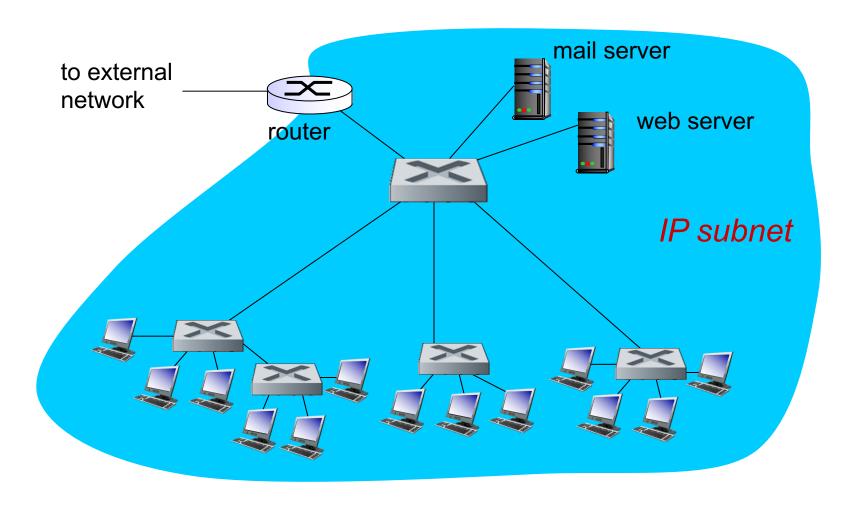

### Self-learning multi-switch example

Suppose C sends frame to I, I responds to C

\* Q: show switch tables and packet forwarding in  $S_1$ ,  $S_2$ ,  $S_3$ ,  $S_4$ 

### Institutional network

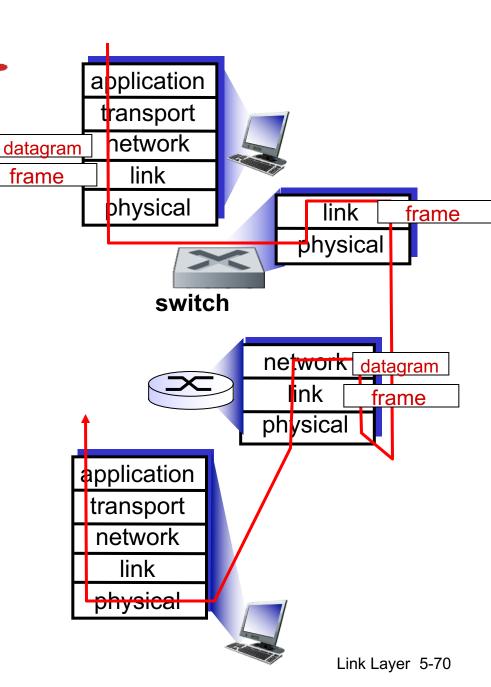

Switches vs. routers

#### both are store-and-forward:

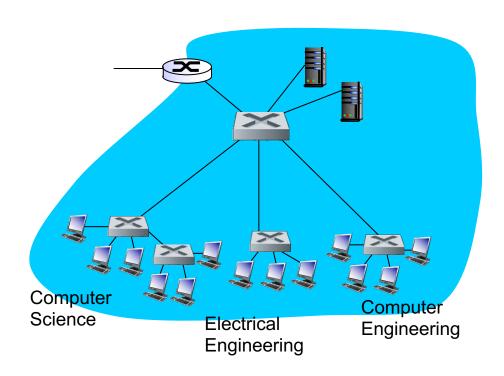

- routers: network-layer devices (examine networklayer headers)
- switches: link-layer devices (examine link-layer headers)

#### both have forwarding tables:

- routers: compute tables using routing algorithms, IP addresses
- switches: learn forwarding table using flooding, learning, MAC addresses

#### **VLANs:** motivation

#### consider:

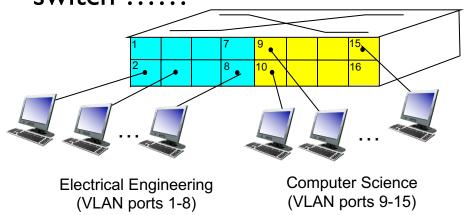

- CS user moves office to EE, but wants connect to CS switch?
- single broadcast domain:
  - all layer-2 broadcast traffic (ARP, DHCP, unknown location of destination MAC address) must cross entire LAN
  - security/privacy, efficiency issues

# **VLANs**

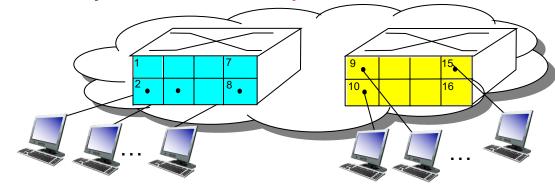

#### Virtual Local Area Network

switch(es) supporting VLAN capabilities can be configured to define multiple *virtual* LANS over single physical LAN infrastructure.

port-based VLAN: switch ports grouped (by switch management software) so that single physical switch ......

... operates as multiple virtual switches

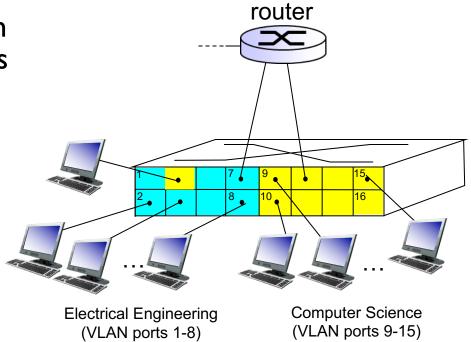

Electrical Engineering (VLAN ports 1-8)

Computer Science (VLAN ports 9-16)

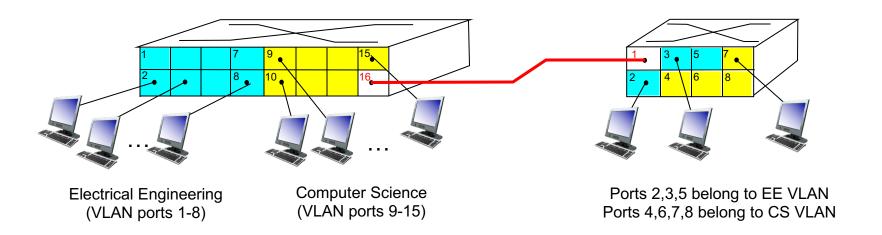

### Port-based VLAN

- traffic isolation: frames to/from ports I-8 can only reach ports
   I-8
  - can also define VLAN based on MAC addresses of endpoints, rather than switch port
- dynamic membership: ports can be dynamically assigned among VLANs

- forwarding between VLANS: done via routing (just as with separate switches)
  - in practice vendors sell combined switches plus routers

### VLANS spanning multiple switches

- trunk port: carries frames between VLANS defined over multiple physical switches
  - frames forwarded within VLAN between switches can't be vanilla 802. I frames (must carry VLAN ID info)
  - 802. I q protocol adds/removed additional header fields for frames forwarded between trunk ports

### 802. I Q VLAN frame format
